Scary venoms from the sea

A toxicologist is studying Australia's deadly marine animals to better understand them — and keep people safe

NST 19/05/24 nls 19.20

IMAGINE feeling like an elephant is sitting on your chest — you can't breathe, there's a sense of impending doom and the pain is so intense you want to die. You've just been stung by a tiny Irukandji jellyfish.

While you are unlikely to die, toxicologist Jamie Seymour of James Cook University in Australia says you'll wish you had. He should know — he's been stung 11 times. But Seymour's job is riskier than most: milking sea creatures of their venom to create life-saving anti-venoms.

Dozens of Irukandji jellyfish, some no bigger than a sesame seed, float in tanks inside a metal shed kept by the university in the state of Queensland. In another tank, there are the most venomous fish in the world: the stonefish.

If its spines pierce your skin, the pain will cause you to lose consciousness and the area around the wound will turn black and die.

The stonefish's venom is powerful enough to kill humans, but there have been no recorded fatalities in Australia.

Seymour is also among those who have survived its sting.

His team is studying Australia's deadliest marine animals in a bid to understand them and keep people safe.

"Australia is without a doubt the most venomous continent in the world," Seymour said, adding: "When you talk to people, especially Americans, they're surprised that we don't all die at birth."

As Seymour moves around the tanks, he points out other deadly animals, including a box jellyfish, which can kill a person within 10 minutes with its poison.

Despite the countless venomous animals across Australia, fatalities are relatively rare. The latest official data show that between 2001 and 2017, there were an average of 32 animal-related deaths a year, with horses and cows the biggest killers.

Since 1883, there have been only two recorded deaths from Irukandji jellyfish and about 70 deaths from box jellyfish.

Anti-venom increasingly needed

By comparison, there were about 4,700 deaths from drug, alcohol and vehicle-related incidents in Australia in 2022 alone, according to government data.

"So, the chances of you being stung by an animal in Australia — or bitten — is reasonable, but the chances of dying very small," Seymour said.

SEARCH FOR ANTI-VENOM

His facility is the only one that milks venom from these deadly marine animals and turns it into anti-venom. For the deadly box jellyfish, that process is tricky. Researchers must remove their tentacles, freeze-dry them and collect the venom once it solidifies.

There's no anti-venom for the Irukandji jellyfish. Instead, doctors treat each symptom as it appears. If you get rapid medical advice, the chance of survival is high.

For the stonefish, the venom extraction process is more challenging. Researchers insert a syringe into a live fish's venom glands, holding it with a towel while they withdraw a thimble full

of the deadly fluid. They then send the venom to a facility in the state of Victoria, which processes it into life-saving anti-venom.

First, the facility staff inject a small amount of venom over six months into an animal, such as a horse, which produces natural antibodies.

The animal's plasma is later removed and the antibodies are extracted, purified and reduced into an anti-venom for humans.

Anti-venoms are shipped to hospitals around Australia and some Pacific islands, where they can be administered if someone is stung or bitten by an animal.

"We have some of the best anti-venoms in the world, there is certainly no doubt about that," Seymour said, noting the time and effort put into producing the serums in Australia.

And anti-venom may be increasingly needed, as climate change can raise the risk of a sting, according to scientists.

THE WORK CONTINUES

About 60 years ago, the Irukandji jellyfish stinging season in Australia was

in November and December.

With ocean temperatures staying warmer for longer, now the jellyfish can linger as late as March.

Warming oceans are also pushing these deadly sea jellies — and other marine animals — further south along the Australian coast. Seymour's students have found that temperature changes can also alter the toxicity of venom.

"For example, if I make an anti-venom for an animal at 20 degrees and I get bitten by an animal that lives in the wild at 30 degrees, that anti-venom isn't going to work," he said.

Studies have also shown that venom from stinging creatures could be used to treat myriad health conditions, including one in which rheumatoid arthritis was effectively cured in mice in two weeks. But this area of research remains largely unfunded, and Seymour says his work continues.

"When you think of the venom, think of it like a vegetable stew. There's a heap of different components in there," he said, adding: "What we've been trying to do is pull these things apart and work out what's going on." AFP
